

under the matrix type liquid crystal device, and the polarization of light transmitted through a polarizer is preferably controlled by each pixel of the matrix type liquid crystal. According to said aspect, the light illuminated on the object to be observed is let in by a microlens array with each pixel of a matrix type liquid crystal device as a pinhole, and makes the first plurality of foci on the object to be observed. Further, since the reflected or fluorescent light from the object to be observed forms the second plurality of foci in the light detecting part, the microscope of the present invention works as a confocal microscope. In this case, as for each pixel of a matrix type liquid crystal device, each pixel of a matrix type liquid crystal device is controlled so that the polarization directions of the light transmitted through each pixel are made mutually orthogonal. Thus, observation of the reflected or fluorescent light from the object to be observed can be made at high speed without scanning control of said object. Also, the cross-talk between multi-confoci can be prevented, so that the resolution is improved.

[0018] Also, a confocal microscope using liquid crystal in accordance with the present invention is comprising: a inlet optical part to let a polarized light from an illuminating light source onto an object to be observed via a beam splitter, a lens, and the first matrix type liquid crystal device provided with a first microlens array on its top part, a light detecting part including an imaging device to detect a reflected or a fluorescent light from an object to be observed via a beam splitter, a lens, and a second matrix type liquid crystal device provided with a second microlens array on its top part; and a control part including a first and a second liquid crystal control subpart to control a polarization direction of a light transmitted through each pixel of said first and second matrix type liquid crystal device, characterized in that it transmits the light passing through said first microlens array from each microlens to each pixel of said first matrix type liquid crystal device, and makes a plurality of foci on said object to be observed, and further, it transmits said reflected or fluorescent light passing through said second microlens array from each microlens array to each pixel of said second matrix type liquid crystal device, and makes a plurality of foci on said imaging device, as well as controls the polarization direction of the light transmitted through

each pixel of said first and second matrix type liquid crystal devices using said first and second liquid crystal control subpart.

[0019] In the aspect mentioned above, the first liquid crystal control subpart of the incident light optical part may preferably control the direction of polarized light passing through each pixel of the first matrix type liquid crystal device to be made mutually orthogonal. Also preferably, the second liquid crystal control subpart of the light detecting part may control the direction of polarized light passing through each pixel of the second matrix type liquid crystal device to be made mutually orthogonal. Also, a polarizer may be located under the first matrix type liquid crystal device, and the direction of polarized light passing through said polarizer may be controlled by each pixel of the first matrix type liquid crystal.

[0020] According to said aspect, the incident light illuminated on the object to be observed is let in by the first microlens array to each pixel of the first matrix type liquid crystal device, and makes the first plurality of foci on the object to be observed. Further, since the reflected or fluorescent light from the object to be observed passes through the second microlens array of the light detecting part and each pixel of the second matrix type liquid crystal device, and forms the second plurality of foci in the light detecting part, the microscope of the present invention works as a confocal microscope. In this case, as for each pixel of the first and the second matrix type liquid crystal devices, each pixel of a matrix type liquid crystal device is controlled so that the polarization directions of the light transmitted through each pixel are made mutually orthogonal. Thus, observation of the reflected or fluorescent light from the object to be observed can be made at high speed without scan control of said object. Also, the cross-talk between multi-confoci can be prevented, so that the resolution in the horizontal and the depth directions is improved. Further, by combination of the first and the second matrix type liquid crystal devices, polarization control, choice of detected signals, and others can be dynamically realized.

[0021] Also, a confocal microscope using liquid crystal in accordance with the present invention is comprising: an inlet optical part to let an amplitude modulated polarized light from an illuminating light source onto an object to be observed via a beam splitter, a matrix type liquid crystal device provided with a microlens array on its top part,

and an objective lens; a light detecting part including an imaging device to detect a reflected or an fluorescent light from the object to be observed via said beam splitter and a lens; and a control part including a liquid crystal control subpart to control each pixel of said matrix type liquid crystal device, and an amplitude modulation control part of said illuminating light source, characterized in that it transmits the light passing through said microlens array from each microlens to each pixel of said matrix type liquid crystal device, and makes a plurality of foci said object to be observed by said objective lens, as well as it controls the polarization directions of the lights transmitted through each pixel of said matrix type liquid crystal device so that they are made mutually orthogonal by using said liquid crystal control subpart, and detects amplitude modulation signals of the reflected or fluorescent light from said object to be observed by transforming them to frequency component signals.

[0022] In the aspect mentioned above, a polarizer is preferably located under a matrix type liquid crystal device, and the polarized light transmitted through said polarizer is controlled by each pixel of the matrix type liquid crystal. Also preferably, the illuminating light source is either single wavelength or multi wavelengths, and the amplitude modulation of the illuminating light source is conducted using either of a matrix type liquid crystal device, an acoustooptic modulator, or a digital mirror device. Also, the amplitude modulation per one wavelength of the illuminating light source may be applied onto each pixel by a plurality of modulated frequency.

[0023] According to said aspect, since the incident light illuminated on the object to be observed is further amplitude modulated, the reflected or fluorescent light from said object can be detected with high sensitivity by signal conversion of the reflected or fluorescent light from said object on the frequency axis. Also, in case that the illuminating light source is multi wavelengths, the reflected or fluorescent light from multi wavelengths can be measured with high sensitivity in short period.

[0024] Also, a confocal microscope using liquid crystal device in accordance with the present invention is comprising: an inlet optical part to let an amplitude modulated polarized light from an illuminating light source onto an object to be observed via a beam

The Claims

What is claimed is:

1. A confocal microscope using liquid crystal, comprising:
an inlet optical part to let a polarized light from an illuminating light source onto an object to be observed via a beam splitter, a matrix type liquid crystal device provided with a microlens array on its top part, and an objective lens;

a light detecting part including an imaging device to detect a reflected or a fluorescent light from the object to be observed via said beam splitter and lens; and

a control part including a liquid crystal control subpart to control each pixel of said matrix type liquid crystal device,

characterized in that it transmits the light passing through said microlens array from each microlens to each pixel of said matrix type liquid crystal device, and makes a plurality of foci on said object to be observed by said objective lens, as well as controls the polarization direction of the light transmitted through each pixel of said matrix type liquid crystal device using said liquid crystal control subpart, and

said liquid crystal control subpart controls polarization directions of the lights transmitted through each pixel of the matrix type liquid crystal device so that they are made mutually orthogonal.

2. The confocal microscope using liquid crystal as set forth in claim 1, characterized in that a polarizer is located in the lower part of said matrix type liquid crystal device and a polarized light transmitted through said polarizer is controlled by each pixel of said matrix type liquid crystal.

3. A confocal microscope using liquid crystal, comprising:
a inlet optical part to let a polarized light from an illuminating light source onto an object to be observed via a beam splitter, a lens, and the first matrix type liquid crystal device provided with a first microlens array on its top part,

a light detecting part including an imaging device to detect a

reflected or a fluorescent light from an object to be observed via a beam splitter, a lens, and a second matrix type liquid crystal device provided with a second microlens array on its top part; and

a control part including a first and a second liquid crystal control subpart to control a polarization direction of a light transmitted through each pixel of said first and second matrix type liquid crystal device,

characterized in that it transmits the light passing through said first microlens array from each microlens to each pixel of said first matrix type liquid crystal device, and makes a plurality of foci on said object to be observed,

and further, it transmits said reflected or fluorescent light passing through said second microlens array from each microlens array to each pixel of said second matrix type liquid crystal device, and makes a plurality of foci on said imaging device, as well as controls the polarization direction of the light transmitted through each pixel of said first and second matrix type liquid crystal devices using said first and second liquid crystal control subpart.

4. The confocal microscope using liquid crystal as set forth in claim 3, characterized in that said first liquid crystal control subpart of said inlet optical part controls polarization directions of the lights transmitted through each pixel of the first matrix type liquid crystal device so that they are made mutually orthogonal.

5. The confocal microscope using liquid crystal as set forth in claim 3, characterized in that said second liquid crystal control subpart of said light detecting part controls polarization directions of the lights transmitted through each pixel of the second matrix type liquid crystal device so that they are made mutually orthogonal.

6. The confocal microscope using liquid crystal as set forth in claim 3, characterized in that, a polarizer is located in the lower part of said first matrix type liquid crystal device, and a polarization direction of the light transmitted through said polarizer is controlled

by each pixel of said first matrix type liquid crystal.

7. A confocal microscope using liquid crystal, comprising:

an inlet optical part to let an amplitude modulated polarized light from an illuminating light source onto an object to be observed via a beam splitter, a matrix type liquid crystal device provided with a microlens array on its top part, and an objective lens;

a light detecting part including an imaging device to detect a reflected or a fluorescent light from the object to be observed via said beam splitter and a lens; and

a control part including a liquid crystal control subpart to control each pixel of said matrix type liquid crystal device, and an amplitude modulation control part of said illuminating light source,

characterized in that it transmits the light passing through said microlens array from each microlens to each pixel of said matrix type liquid crystal device, and makes a plurality of foci said object to be observed by said objective lens, as well as it controls the polarization directions of the lights transmitted through each pixel of said matrix type liquid crystal device so that they are made mutually orthogonal by using said liquid crystal control subpart, and detects amplitude modulation signals of the reflected or fluorescent light from said object to be observed by transforming them to frequency component signals.

8. The confocal microscope using liquid crystal as set forth in claim 7, characterized in that a polarizer is located in the lower part of said matrix type liquid crystal device, and an polarized light transmitted through said polarizer is controlled by each pixel of said matrix type liquid crystal.

9. The confocal microscope using liquid crystal as set forth in claim 7, characterized in that said illuminating light source is of either single wavelength or multi wavelengths, and said illuminating light source is amplitude modulated by using either a matrix type liquid crystal device, an acoustooptic modulator, or a digital mirror device.

10. The confocal microscope using liquid crystal as set forth in claim 7 or 9, characterized in that, the amplitude modulation for each wavelength of said illuminating light source is applied to each pixel by a plurality of modulation frequency.

11. The confocal microscope using liquid crystal as set forth in claim 7, characterized in that, the conversion of amplitude modulation signals of the reflected or fluorescent light from said object to be observed to frequency signals is operation-processed by high speed Fourier transform.

12. A confocal microscope using liquid crystal, comprising:

a inlet optical part to let an amplitude modulated polarized light from an illuminating light source onto an object to be observed via a beam splitter, a lens, and a first matrix type liquid crystal device provided with a first microlens array on its top part,

a light detecting part including an imaging device to detect a reflected or a fluorescent light from the object to be observed via a beam splitter, a lens, a second matrix type liquid crystal device provided with a second microlens array on its top part, and a condenser lens; and

a control part including a first and a second liquid crystal control subpart to control a polarization direction of a light transmitted through each pixel of said first and second matrix type liquid crystal device,

characterized in that it transmits the light passing through said first microlens array from each microlens to each pixel of said first matrix type liquid crystal device, and makes a plurality of foci on said object to be observed,

and further, it transmits said reflected or fluorescent light passing through said second microlens array from each microlens array to each pixel of said second matrix type liquid crystal device, and makes a plurality of foci on said imaging device, as well as controls the polarization direction of the light transmitted through each pixel of said first and second matrix type

liquid crystal devices using said first and second liquid crystal control subpart, and detects amplitude modulation signals of the reflected or fluorescent light from said object to be observed by converting them to frequency signals.

13. The confocal microscope using liquid crystal as set forth in claim 12, characterized in that, said first liquid crystal control subpart of said inlet optical part controls polarization directions of the lights transmitted through each pixel of said first matrix type liquid crystal device so that they are made mutually orthogonal.

14. The confocal microscope using liquid crystal as set forth in claim 12, characterized in that, said second liquid crystal control subpart of said light detecting part controls polarization directions of the lights transmitted through each pixel of said second matrix type liquid crystal device so that they are made mutually orthogonal.

15. The confocal microscope using liquid crystal as set forth in claim 12, characterized in that, a polarizer is located in the lower part of said first matrix type liquid crystal device, and the polarized light transmitted through said polarizer is controlled by each pixel of said matrix type liquid crystal.

16. The confocal microscope using liquid crystal as set forth in claim 12, characterized in that, said illuminating light source is of either single wavelength or multi wavelengths, and said illuminating light source is amplitude modulated by using either a matrix type liquid crystal device, an acoustooptic modulator, or a digital mirror device.

17. The confocal microscope using liquid crystal as set forth in claim 12 or 16, characterized in that, the amplitude modulation for one wavelength of said illuminating light source is applied to each pixel by a plurality of modulation frequency.

REPLACED BY
APT 34.71.07

18. The confocal microscope using liquid crystal as set forth in claim 12, characterized in that the transform from the amplitude modulation signal of the reflected or fluorescent light of said object to be observed to frequency signal is processed by Fast Fourier Transform.

19. The method of measuring fluorescence from a microarray substrate by a confocal microscope using liquid crystal, characterized in that for the fluorescence measurement of a microarray substrate with a fluorescent material as a selective marker given in advance, the fluorescence from said fluorescent material is observed by using a confocal microscope using liquid crystal as set forth in any one of claims 1 to 18.

20. The method of measuring fluorescence from a microarray substrate by a confocal microscope using liquid crystal as set forth in claim 19, characterized in that said microarray substrate contains a minute amount of DNA or a biological material.

21. The method of measuring fluorescence from a microarray substrate by a confocal microscope using liquid crystal as set forth in claim 19 or 20, characterized in that, said microarray substrate is a DNA chip.

22. The method of measuring polarized light by said confocal microscope, characterized in that for measuring polarized light from the reflected or fluorescent light from an object to be observed, the polarized light from said object to be observed is measured by using a confocal microscope using liquid crystal as set forth in any one of claims 1 to 18.

23. The method of measuring polarized light by the confocal microscope using liquid crystal as set forth in claim 22, characterized in that in the liquid crystal matrix of said confocal microscope using liquid crystal, the polarized light from said object to be observed is

measured by rotating said polarized light by 180 degrees.
